## 1 Data file

Suppose we have some data in a file:

```
C
-0.3427
                                          D
                                       -0.1613
                                                    -0.8472
-0.5253
            -0.9315
-0.9740
            -0.2558
                         -0.5622
                                       -0.7635
                                                    -0.0914
                         -0.4818
-0.3846
0.3841
0.9216
0.6217
             0.7702
                                       0.2155
-0.7904
0.5241
                                                     0.2967
0.9166
0.1006
            -0.3162
                                                    -0.6530
0.6207
             -0.9299
                           0.4837
                                        0.5755
                                                    -0.6024
0.4278
             -0.0014
                          0.8184
                                        0.9382
                                                    -0.1449
                          -0.7532
0.0545
-0.9178
             0.2612
                                        0.3901
                                                    -0.0075
0.2134
             0.6217
                                        0.6980
                                                    -0.2172
                          -0.1969
-0.9529
              0.8989
                                       -0.3079
                                                    0.0389
0.8311
              0.0145
                           0.4215
                                       -0.5451
                                                    -0.3415
```

## 2 Program

The following program (which breaks a page) reads the data in the file and performs analysis:

```
#!/usr/bin/env python

import numpy as np

def readfile(filename):
    """Read tabular data from file and return as numpy array."""

f = open(filename, 'r')
    data = [] # list of rows in table
    for line in f:
        if line.startswith('#'):
```

```
continue # drop comment lines
           numbers = [float(w) for w in line.split()]
           data.append(numbers)
13
        return np.array(data)
    def analyze(data):
        """Return statistical measures of an array data."""
        return np.mean(data), \
              np.std(data), \
19
              np.corrcoef(data)
    if __name__ == '__main__':
        data = readfile('mydat.txt')
        # Treat each column as a variable
        m, s, c = analyze(data.transpose())
25
        print """
    mean=%f
    st.dev=%f
    correlation matrix:
    """ % (m, s, c)
```

The output becomes

```
Terminal> python fileread.py
mean = -0.006005
st.dev=0.583542
correlation matrix:
[[ 1.
             0.0509676
                        0.52406366 0.20964645 0.1574504 ]
 [ 0.0509676
                       -0.30920845 -0.12129049 0.7611538 ]
             1.
 [ 0.52406366 -0.30920845 1.
                                   0.49355806 -0.42263817]
 [ 0.20964645 -0.12129049  0.49355806  1.
                                             -0.38286589]
             [ 0.1574504
```

## 3 Fortran example

Here is an example of a Fortran 77 snippet:

```
subroutine process(a, n, c, r)

C Return array r = c*a
  integer n
  real*8 a(n), c, r(n)
```

```
integer i
    do i = 1,n
        r(i) = c*a(i)
end do
return
end
```
