---

## Goal

The primary goal of this demo talk is to demonstrate how to write talks with DocOnce and get them rendered in numerous HTML formats.

### Layout
This version utilizes beamer slides with the theme `red_plain`.

---

## Problem setting and methods

---

## We aim to solve the (almost) simplest possible differential equation problem

$$u'(t) = -au(t) \qquad (1)$$
$$u(0) = I \qquad (2)$$

Here,

- $t \in (0, T]$
- $a$, $I$, and $T$ are prescribed parameters
- $u(t)$ is the unknown function
- The ODE (1) has the initial condition (2)

---

## The ODE problem is solved by a finite difference scheme

- Mesh in time: $0 = t_0 < t_1 \cdots < t_N = T$
- Assume constant $\Delta t = t_n - t_{n-1}$
- $u^n$: numerical approx to the exact solution at $t_n$

The $\theta$ rule,

$$u^{n+1} = \frac{1 - (1-\theta)a\Delta t}{1 + \theta a \Delta t} u^n, \quad n = 0, 1, \ldots, N-1$$

contains the Forward Euler ($\theta = 0$), the Backward Euler ($\theta = 1$), and the Crank-Nicolson ($\theta = 0.5$) schemes.

---

## The Forward Euler scheme explained

## Implementation

### Implementation in a Python function:

```python
def solver(I, a, T, dt, theta):
    """Solve u'=-a*u, u(0)=I, for t in (0,T]; step: dt."""
    dt = float(dt)                   # avoid integer division
    N = int(round(T/dt))             # no of time intervals
    T = N*dt                         # adjust T to fit time step dt
    u = zeros(N+1)                   # array of u[n] values
    t = linspace(0, T, N+1)          # time mesh

    u[0] = I                         # assign initial condition
    for n in range(0, N):            # n=0,1,...,N-1
        u[n+1] = (1 - (1-theta)*a*dt)/(1 + theta*dt*a)*u[n]
    return u, t
```

## How to use the solver function

### A complete main program

```python
# Set problem parameters
I = 1.2
a = 0.2
T = 8
dt = 0.25
theta = 0.5
|\pause|

from solver import solver, exact_solution
u, t = solver(I, a, T, dt, theta)
|\pause|

import matplotlib.pyplot as plt
plt.plot(t, u, t, exact_solution)
plt.legend(['numerical', 'exact'])
plt.show()
```
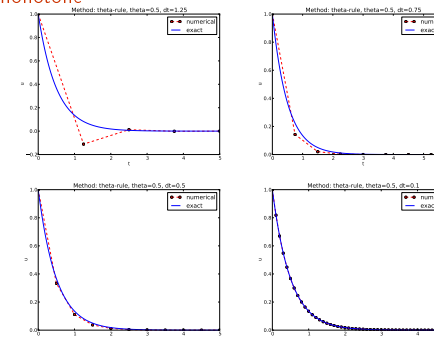

## Results

## The Crank-Nicolson method shows oscillatory behavior for not sufficiently small time steps, while the solution should be monotone

## The artifacts can be explained by some theory

Exact solution of the scheme:

$$u^n = A^n, \quad A = \frac{1-(1-\theta)a\Delta t}{1+\theta a\Delta t}.$$

Key results:

- Stability: $|A| < 1$
- No oscillations: $A > 0$
- $\Delta t < 1/a$ for Forward Euler ($\theta = 0$)
- $\Delta t < 2/a$ for Crank-Nicolson ($\theta = 1/2$)

### Concluding remarks:
Only the Backward Euler scheme is guaranteed to always give qualitatively correct results.
